## Overview

1. Motivation for empirical Risk Analysis of sociotechnical systems in ATM
2. Introduction to a new concept for Risk Analysis
3. Empirical Concept Evaluation
4. Results
5. Conclusions for further research

Definition of Risk:

*"Risk is defined as the probability that an accident occurs during a stated period of time"*

Blom (2003)

## Motivation for the proof of concept study

- The predictive Risk Analysis on sociotechnical systems provide valuable estimations on the resulting ATM safety-performance
- Traditional Risk Analysis rely on expert statements (subjective estimation)
- New concepts for model-based risk analysis have been evaluated (objective estimation). No direct evidence from current operations for validation.
- A pure empirical approach for Risk Analysis by means of Human-In-The-Loop Simulations often lacks statistic power when proving the system-safety against rare safety-critical events.
- An approach is needed that indicates risk predictively by objective measures
- A Human-In-The-Loop approach is proposed for an empiric approach for Risk Analysis

## Using visual cue perception as a risk indicator

- Why using actions of the operator for visual cue perception as risk indicators?
  - Operators involve visual information essentially for decision-making in safety-critical situations (e.g. virtual tower, flare initiation)
  - We assume the safe decision-making as being strongly sensitive to the design of the visual provision of the traffic situation.
  - There is a trend of computerization and automation in tower and flight deck operations, involving increasingly the visual stimulation for information perception in ATM (e.g. datalink and A-SMGCS).
- Visual Cue Perception indicates the contribution of the system design to risk.

control

## The proof of concept study

- The objective is
  - To develop a concept for a methodology that identifies the safety-relevance of visual cues
  - To identify the relative importance of visual cues within a set of visual cues
  - To determine the relative contribution to risk by a specific visual cue

## Introduction to the concept - Assumptions

- A system provides a set of cues visually to an operator
- The accident event as well as the related precursors (e.g. loss-of-separation or runway incursion) are defined as safety-relevant events
- The visual cue  $k$  might cause a safety-relevant event in the case of failed perception
- The unification of all failed perception events determines the resulting probability of the safety-relevant events

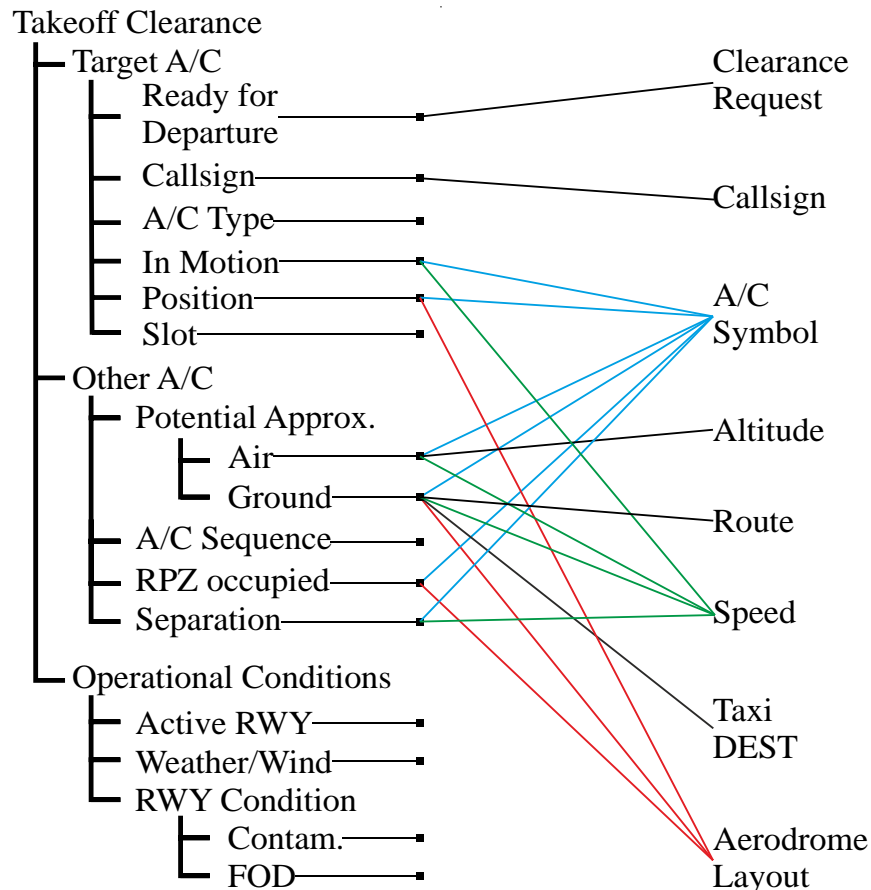

## The Human-In-The-Loop Simulation approach

- An A-SMGCS-SMAN HMI serves as a test setup at Frankfurt airport
- Novices are selected as test persons (4 trained students, each one tested 10 hours), acting as tower controllers
- Measuring methods
  - Regular (periodic) questionnaires for the importance of visual cue when granting take-off clearances → demand of visual cues
  - Detecting runway incursions → runway incursion rate
  - In the case of a detected runway incursion: Instant (closed ended) questionnaire for the identification of the related visual cue that was not perceived adequately → Identification of the safety-relevance
  - Eye tracking measures → demand of visual cues

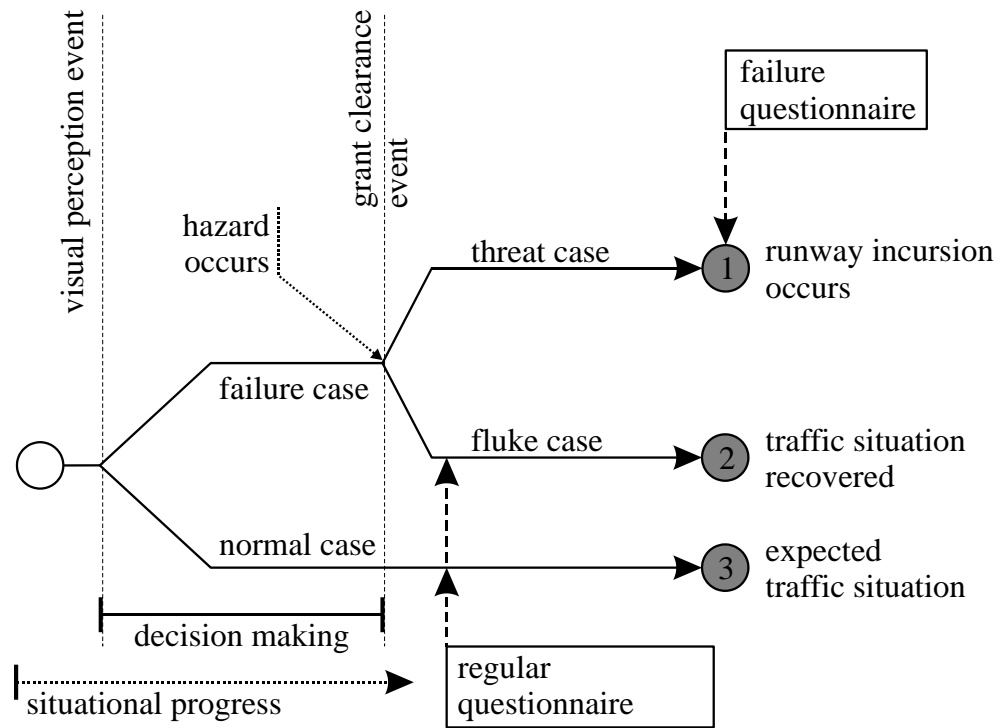

# Modeling the visual demand in aerodrome control: The take-off clearance

## Models bases upon

- Manual of operations (DFS)
- ICAO PANS-ATM Doc 4444
- Task Analysis in the scope of Virtual Tower research
  - Expert Judgment
  - Field evaluation

# Event tree of the decision-making „take-off clearance“

## The test setup

### ➤ Surface Movement Manager

## Results – Regular questionnaire $h_{VP_k}$

- Subjective rating of the importance of proposed visual cues on a scale from 1 (no agreement) to 4 (total agreement)

## Results – Failure questionnaire $h_{PF_k|RI}$

- Subjective rating of the contribution to runway incursion (yes/no-options)

## Contribution of a visual cue to risk

- $VP_k$  Perception event of the visual cue  $k$ .
- $PF_k$  Perception failure event of the visual cue  $k$
- $RI$  Runway Incursion event
- $p_{PF_k|RI}$  Conditional probability of failed perception  $k$  when  $RI$  has occurred (event tree case 1) → failure questionnaire  $h_{PF_k|RI}$
- $p_{VP_k}$  Probability to use the visual  $k$  for granting the take-off clearance  
→ regular questionnaire  $h_{VP_k}$

$$P(RI|VP_k) = \frac{p_{PF_k|RI}}{p_{VP_k}} \cdot p_{RI}$$

## Results

Visual cue	$P(RI VP_k)$
Route (other a/c)	3.0 %
Position (other a/c)	2.6 %
Heading (other a/c)	2.4 %
Speed (other a/c)	2.4 %
Speed (target a/c)	2.1 %
Route (target a/c)	2.0 %
Altitude (other a/c)	2.0 %
Position (target a/c)	1.4 %
Heading (target a/c)	0.6 %
Altitude (target a/c)	? ( $p_{VP_k} = 0$ )

## Conclusion

- Questionnaires give valuable clues on the importance the demanded cues.
- The safety-relevance of visual cues was determined by the Failure Questionnaires. This offers a data-basis for further design evaluation early in the product life-cycle
- A contribution to risk by a specific visual cue could be quantified. It suffers of non-calibrated estimates which might impair the results accuracy.
- The results of the Proof-of-concept study has little external validity as the novice test persons have no reference to real operations.
- Further research will concentrate on more objective measures of the visual cue perception, e.g. eye tracking analysis.
